1. GENERAL

1.1 Requirement for braking

When you want to slow down a running asynchronous motor fed by a frequency converter it turns into a generator, feeding energy back into the frequency converter. The energy increases the voltage in the DC-link. The frequency converter compensates for this increase by increasing the output frequency, decreasing the instantaneous slip and increasing the motor load.

The deceleration is, in this case, dependent on the power losses in the converter and in the motor. This is usually sufficient in most cases, for pumps, fans, conveyors etc. where the kinetic energy in the load is small or the braking time is not critical.

When you have to brake the motor faster than the losses allow, you have to use an external brake resistor for energy dissipation together with an internal, factory-mounted brake chopper. The extra energy from the load is turned into heat in the brake resistor.

Applications where dynamic braking is usually needed include centrifuges, cranes, some conveyors and drives requiring very fast reversing.

1.2 Brake components

The brake chopper is an extra IGBT mounted into the NX frequency converters at the time of manufacturing. Smaller drives (FR4 to FR6 and MF4 to MF6) contain it as standard. If the DC link voltage increases too much, the brake IGBT turns on and discharges the capacitors through the brake resistor. The brake chopper in the NX frequency converter ranges is rated for continuous drive rated power.

The brake resistor is an external, low impedance resistor. In order to achieve the correct power handling capacity for a specific application, resistors can be connected in series and parallel, keeping within the limits in Table 7.

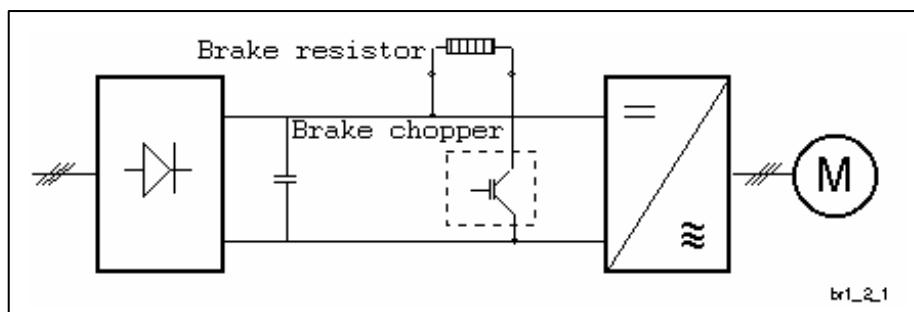

Figure 1. The brake components and their basic connection

1.3 Classes of use

a) *Partial use (most typical)* {tc "a) Partial use (most common)"}

The process requires regular or irregular rapid decelerations, stops or reversings.

b) *Continuous use* {tc "b) Continuous use"}

The motor continuously brakes with constant torque.

c) *Combination use* {tc "c) Combination use"}

The motor continuously brakes with variable torque.

d) *DC-link voltage smoothing* {tc "d) DC-link voltage smoothing"}

The brake resistor smooths overvoltage spikes from the supply.

2. TECHNICAL DATA

2.1 Standard resistors for partial use

Brake resistors for partial use for the NX ranges for 208...240V, 380...500V and 525...690V supply voltages can be chosen from the tables below.

For the NX_5 range we have predefined two ranges of brake resistors, one for heavy duty and one for light duty. The heavy duty resistor is sized for a 3-second full power braking with a 7-second ramp to zero. The light duty resistor is rated for a 5-second ramp from full power to zero. See Figure 2.

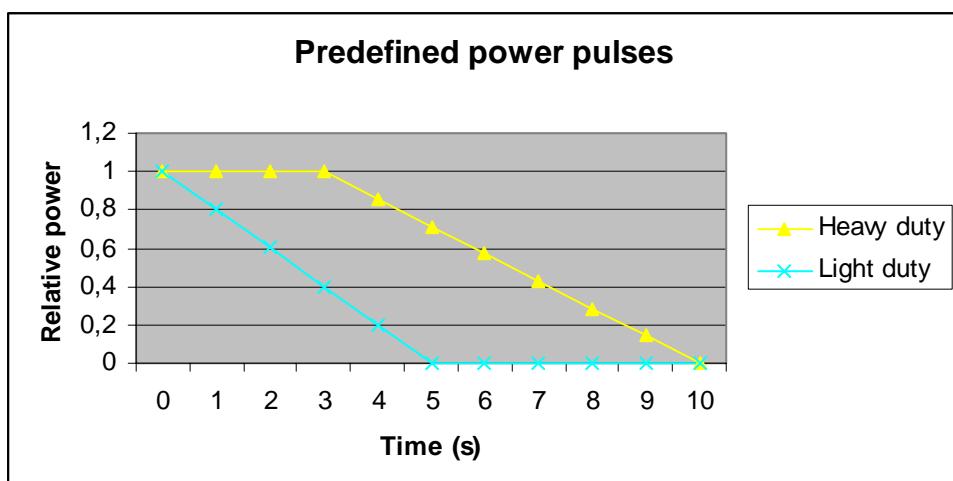

Figure 2. Heavy and light duty braking definitions.

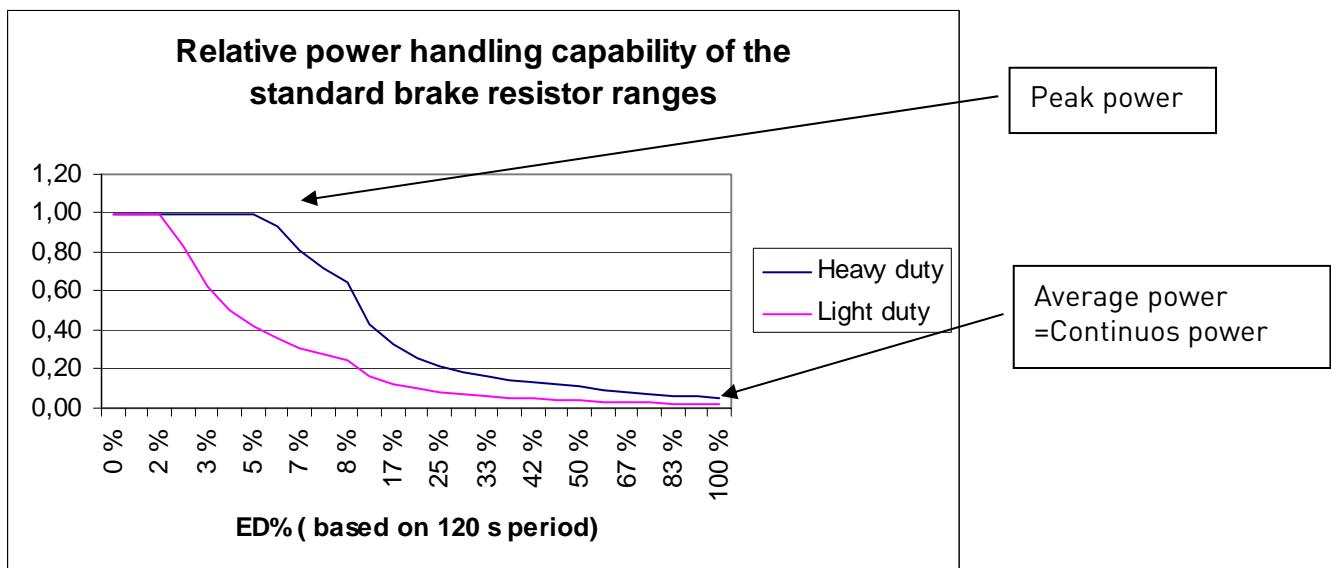

Figure 3. Peak and average power definitions.

2.1.1 380...500V range

Light duty		Energy [kJ]	Average power [kW]
Type code	Resistance	5 sec full torque braking	1 pulse/2 min
BRR 0022 LD 5	63	28	0.24

2.2 Other resistors

Should other types of resistors be used, make sure that the resistance is higher than the minimum resistance defined. The power handling capacity must be sufficient for the application.

The minimum resistances calculated at the trip level (NX_5: 911VDC, NX_2: 437VDC and NX_6: 1200VDC) can be found in the following tables.

380...500V range			208...240V range

2.4 Environment

Surface temperature of the resistor box	<80°C
Maximum ambient temperature	30°C
Protection class	IP20, IP21, IP50

NOTE: On mounting the resistor package, note the high surface temperature (up to 200 °C). The mounting surface must be non-flammable and there must be sufficient free space around the resistor (100 mm).

The resistors are designed for natural convection cooling in a free space; ensure sufficient ventilation of the area.

2.5 Thermal protection for the LD resistors

Holder for thermal protection

3. CHOICE OF BRAKE RESISTOR

3.1 General

When you choose the brake resistor for your drive, start from the requirements of the process/drive. The choice of brake resistor is influenced by

- a) *the average braking power during one cycle*; this defines the power dissipation required of the brake resistor
- b) *the maximum power dissipation*; this defines the instantaneous power handling capacity of the brake resistor and
- c) *the maximum current of the brake IGBT*; this defines the minimum resistance for the brake resistor.

Vacon Technical Support will assist you in all matters concerning braking.

3.2 Sizing principles

All rotating parts contain kinetic energy. When the load is braked, the energy difference between the higher speed and the lower speed must be dissipated somewhere. Some of the energy is used in the losses of the motor and the frequency converter, but the majority must be dissipated in the brake resistor.

The energy of a load at speed n is given by the formula:

$$E = \frac{1}{2} J \omega^2$$

where

J is the moment of inertia of the load (in kgm^2) and

ω is the rotating speed of the load (in radians/s)

In engineering units

$$E = \frac{1}{182,3} J n^2$$

where n is the rotating speed (in 1/min)

The difference between the energy at two speeds is thus

$$\Delta E = E_1 - E_2 = \frac{1}{182,3} J (n_1^2 - n_2^2) = \frac{1}{2} J (\omega_1^2 - \omega_2^2)$$

The average power required is

$$P = \frac{\Delta E}{t}$$

where t is the braking time.

If the load has a cycle with a total cycle time t_c , the average power of the cycle is

$$P = \frac{\Delta E}{t_c}$$

The chosen resistor must be able to handle this power. If the braking time is longer than 1 minute, the resistor must be sized for the continuous braking power.

3.2.1 Calculating braking time

The time required to accelerate or brake a load can be calculated as follows:

The basic equation is:

$$T = J \frac{d\omega}{dt}$$

where T is the required torque.

The time required to change the speed of a load is

$$\Delta t = J \frac{\omega_1 - \omega_2}{T}$$

or the torque required to change the speed in time t is

$$T = J \frac{\omega_1 - \omega_2}{t}$$

The available torque consists of the torque generated by the motor T_{motor} and the braking torque generated by the load and friction in it T_{load} .

$$T_{total} = T_{motor} + T_{load}$$

In many cases the frictional torque is sufficient to brake the load, it might even be too high, so the motor must drive the load even if the speed is slowing down.

This torque required from the motor should be compared to the rated torque of the motor:

$$T = 9550 \frac{P}{n}$$

If the rated torque is higher, the motor can perform the required acceleration/deceleration.

3.2.2 Calculating the moment of inertia

The moment of inertia as 'seen' by the motor consists of the motor inertia plus the load inertia, changed by the gear ratio as follows:

$$J_{tot} = J_{motor} + g^2 J_{load}$$

where g is the gear ratio, J_{motor} is the motor inertia and J_{load} is the load inertia. The ratio g is > 1 if the load speed is higher than the motor speed and < 1 if the load speed is lower than the motor speed.

In many cases the moment of inertia of the motor is very small compared to the moment of inertia of the load. Only in cases where the load turns very slowly (i.e. the gear ratio is low) the motor inertia is significant.

The moment of inertia of typical shapes is shown in Figure 5

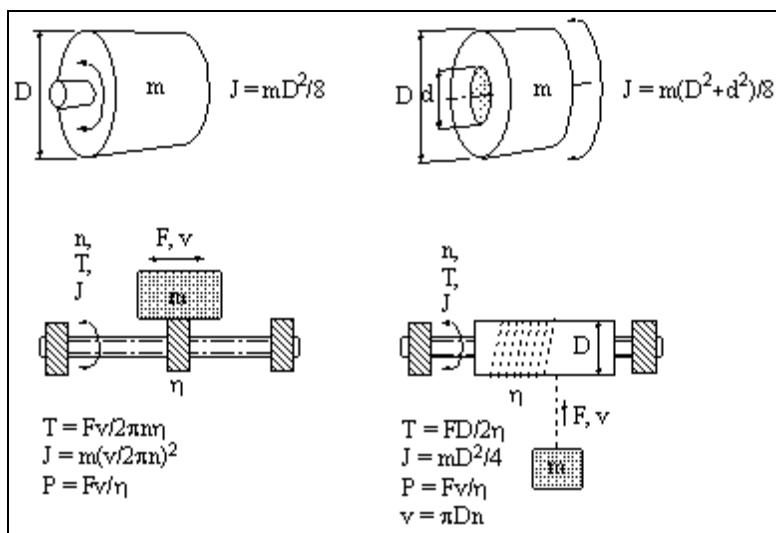

Figure 5.

The moment of inertia of a specific machine is often specified on the rating plate. Otherwise the manufacturer is responsible to give this information.

Sizing procedure:

1. Maximum speed	n_1		rpm
2 Minimum speed	n_2		rpm
3 Moment of inertia = $J_{tot} = J_{motor} + g^2 J_{load}$ g = gear ratio	J		$k\text{gm}^2$
4 Energy to be dissipated	$\Delta E = E_1 - E_2 = \frac{1}{182,3} J(n_1^2 - n_2^2)$		kJ
5 Braking time	t		s
6 Braking power	$P = \frac{\Delta E}{t}$		kW
7 Determine duty cycle for braking t_1 = duration of cycle – assumption 120 s.	$f = \frac{t}{t_1}$		

8 Determine average power for the resistor	$P_{ave} = fP$		kW
9 Calculate the relative power required. P_{res} = peak power of chosen resistor	$P_{rel} = \frac{P_{ave}}{P_{res}}$		%
10 Verify that the pair of values in 7 and 9 are within limits for the chosen resistor – see Figure 5			
7 Calculate the braking torque required	$T = J \times 0,105 \times \frac{n_1 - n_2}{t}$		Nm
8 Verify motor rated torque > required torque P_M in kW n_M in rpm	$T_M = 9550 \times \frac{P_M}{n_M}$		Nm

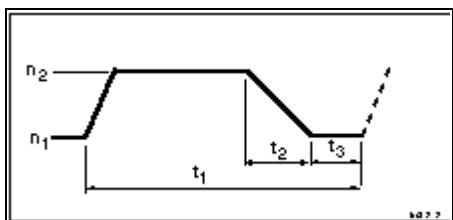

Figure 6. Speed profile of one drive cycle.

t_1 = length of cycle

t_2 = deceleration time

t_3 = stop time

n_1 = minimum speed of motor

n_2 = maximum speed of motor

The relative power handling capability of the standard resistor ranges is shown in the figure below:

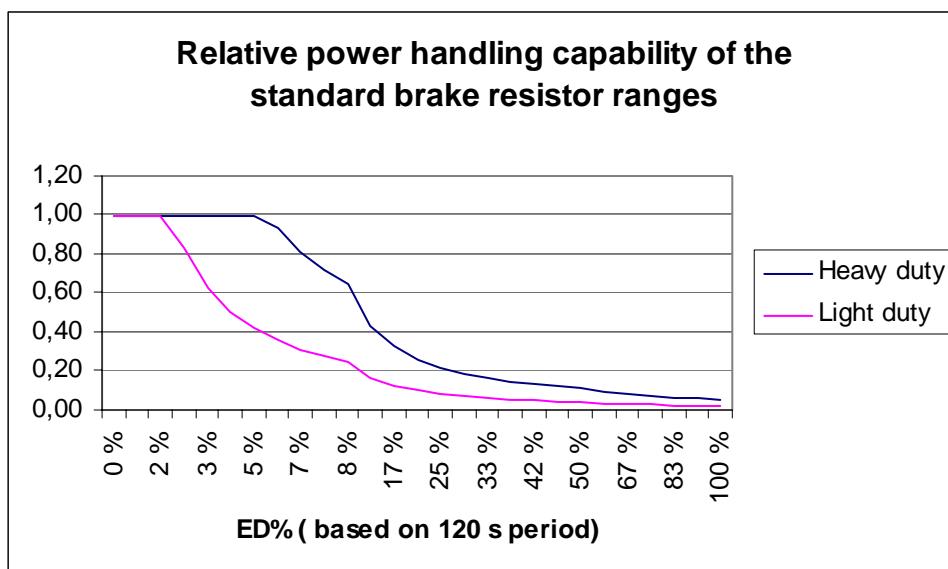

Figure 7.

3

Verify the following:

- The chosen resistor type can handle the required power (NOTE: As the brake IGBT current is limited by the device, a resistance with a smaller impedance than the minimum specified for the drive cannot be used).
- If this is not the case, the resistor has to be sized specifically for the application. In many cases a suitable combination of series and parallel connection of standard resistances may be the solution, in others a special resistor must be defined and manufactured.

3.2.3 Internal resistors

Frame sizes FR4, FR5 and FR6 (380...500V) drives can be equipped with an internal brake resistor as a factory option. The resistors are designed for a 2s full torque braking from nominal motor speed to zero or a 1 second full power braking every minute.

Type code	Resistance []	Energy 2s full torque braking [kJ]	Average power 1 pulse/min [W]
NX_5 FR4	120	4	45
NX_5 FR5	55	8.9	100

Table 8.

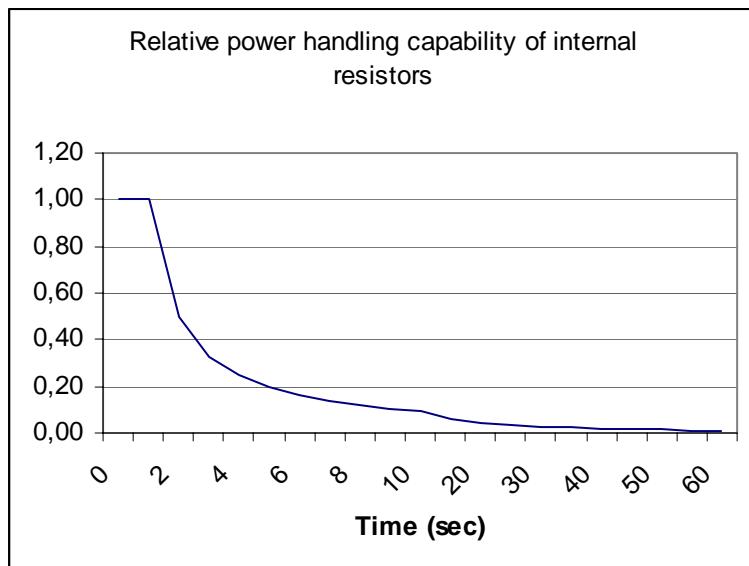

Figure 8.

4. CONNECTIONS

4.1 General

Make sure that your frequency converter is equipped with a brake chopper. This is a factory installed option!

The brake resistor is connected to the DC+ and R- connectors on the frequency converter.

The minimum cable sizes are shown in Table 1 and Table 2. When you size the cables, note that the input fuses of the converter also protect this cable.

Avoid running the brake resistor cable too near other cables. The recommended minimum distance to e.g. the control cables is 0.5 meters.

Note: Disconnect the frequency converter from the mains when connecting the brake resistor. Wait a further 5 minutes before opening the frequency converter cover. Perform measurements to ensure that no voltage is present on the DC and R- connectors.

Read Chapter 1, SAFETY, in Vacon NX User's Manual.

Cable sizing

M8 = M8 bolt on the resistor

Only two conductors of a normal three phase cable are needed. The shield of the cable should be connected at each end. The third, unused connector should also be grounded by connecting it to ground at one end.

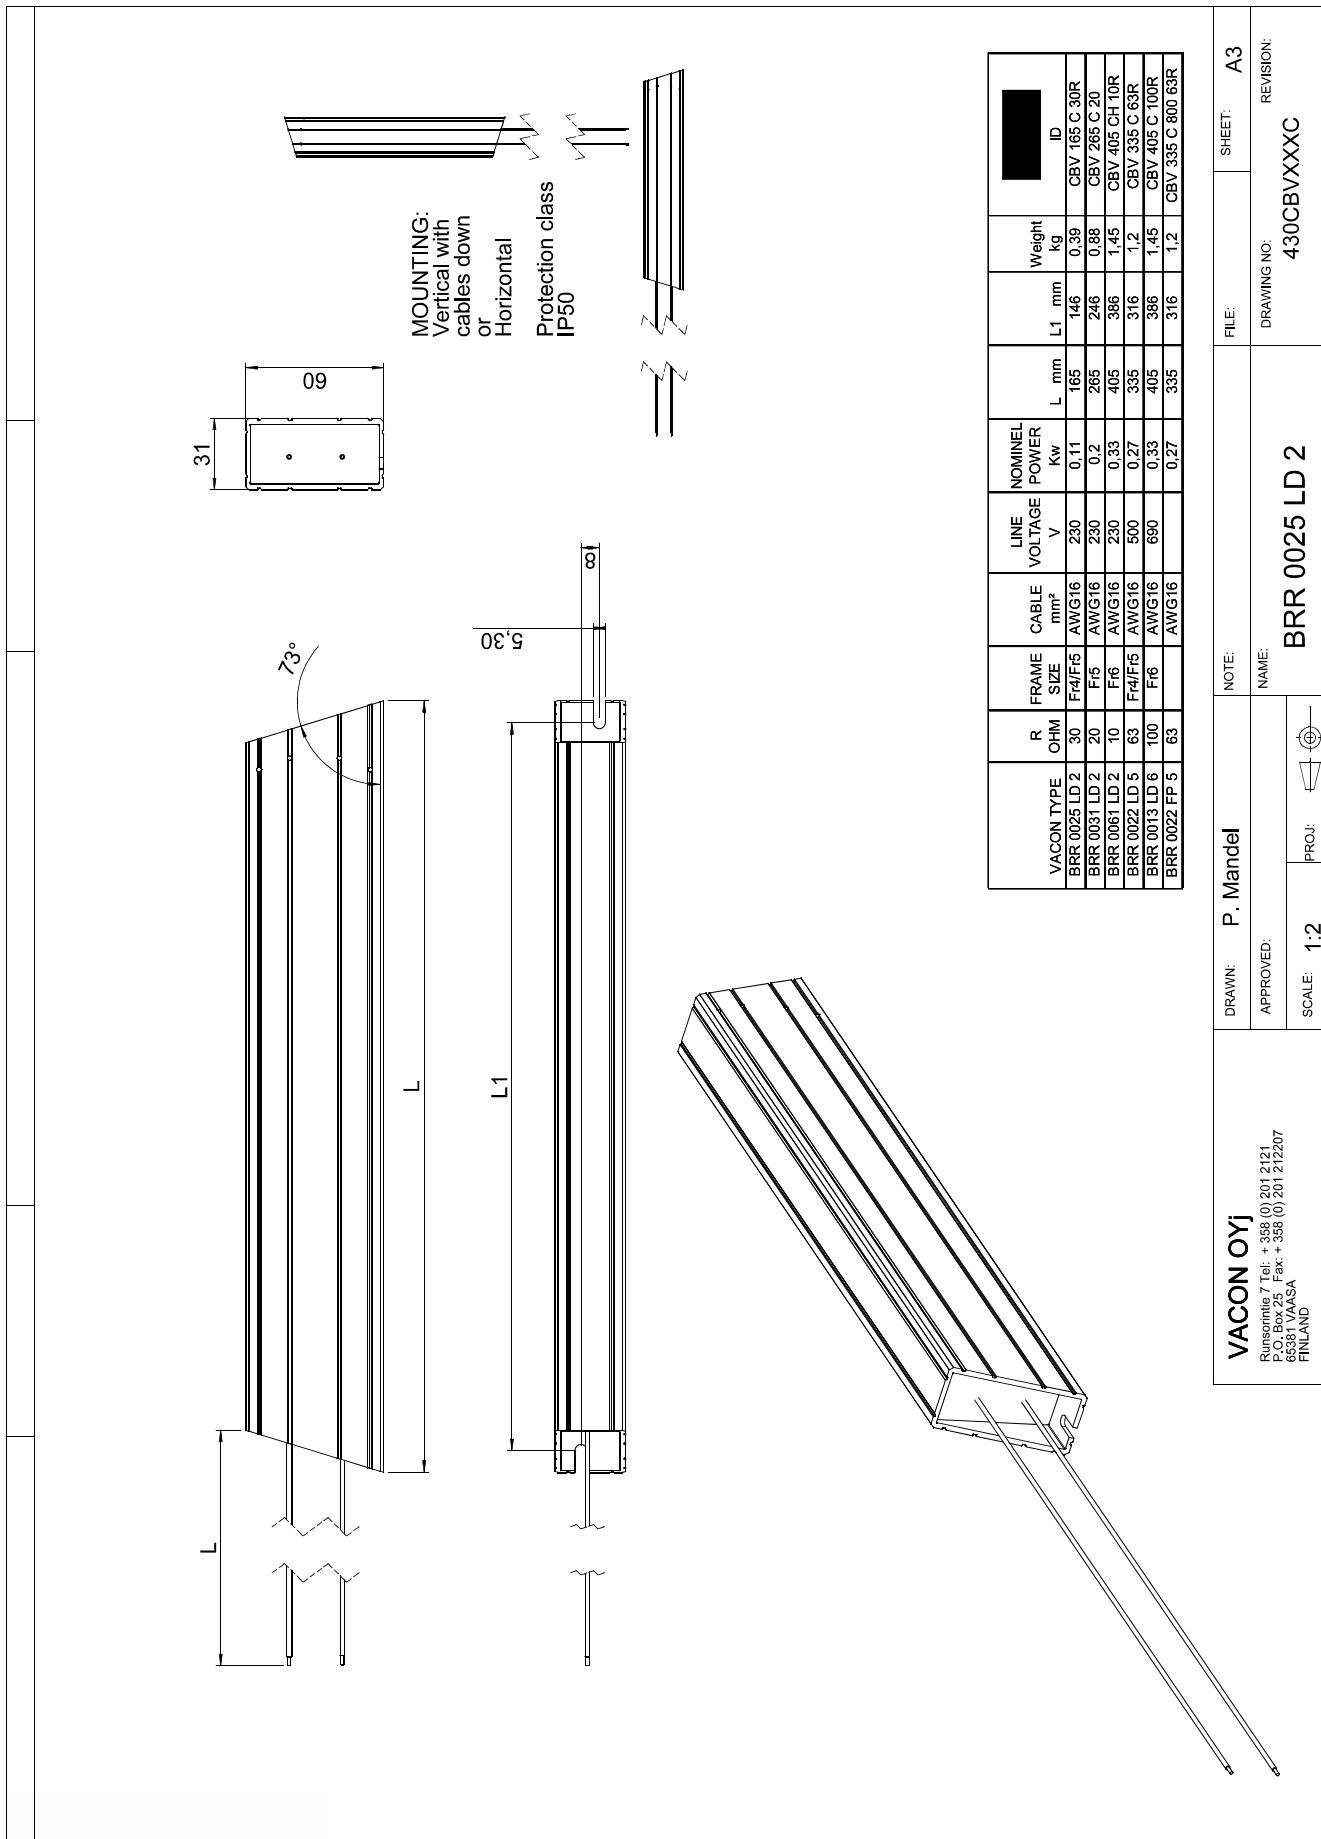

Cable sizes:

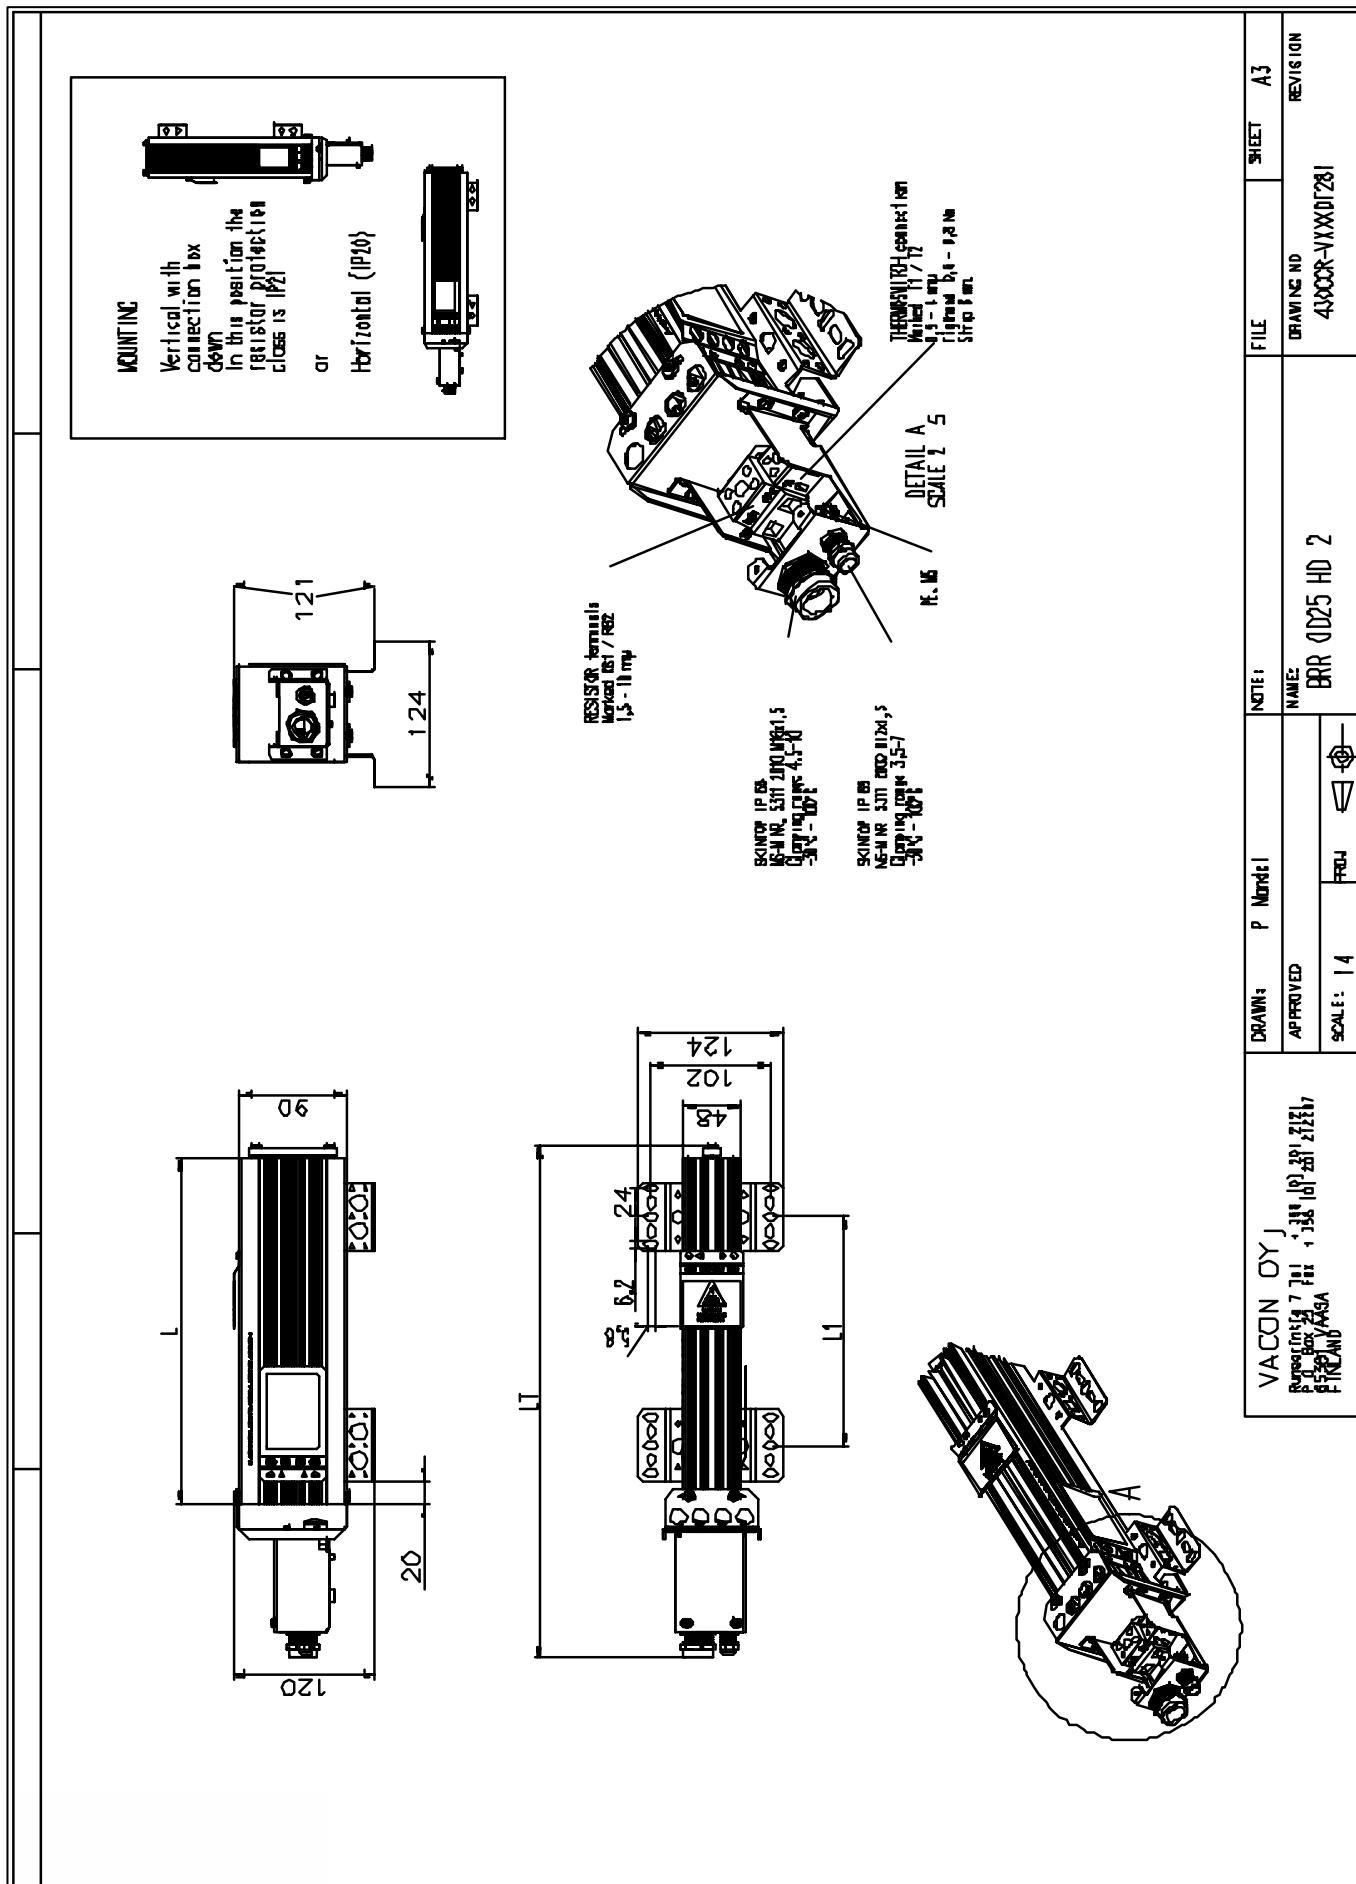

AWG	mm ²
Size	

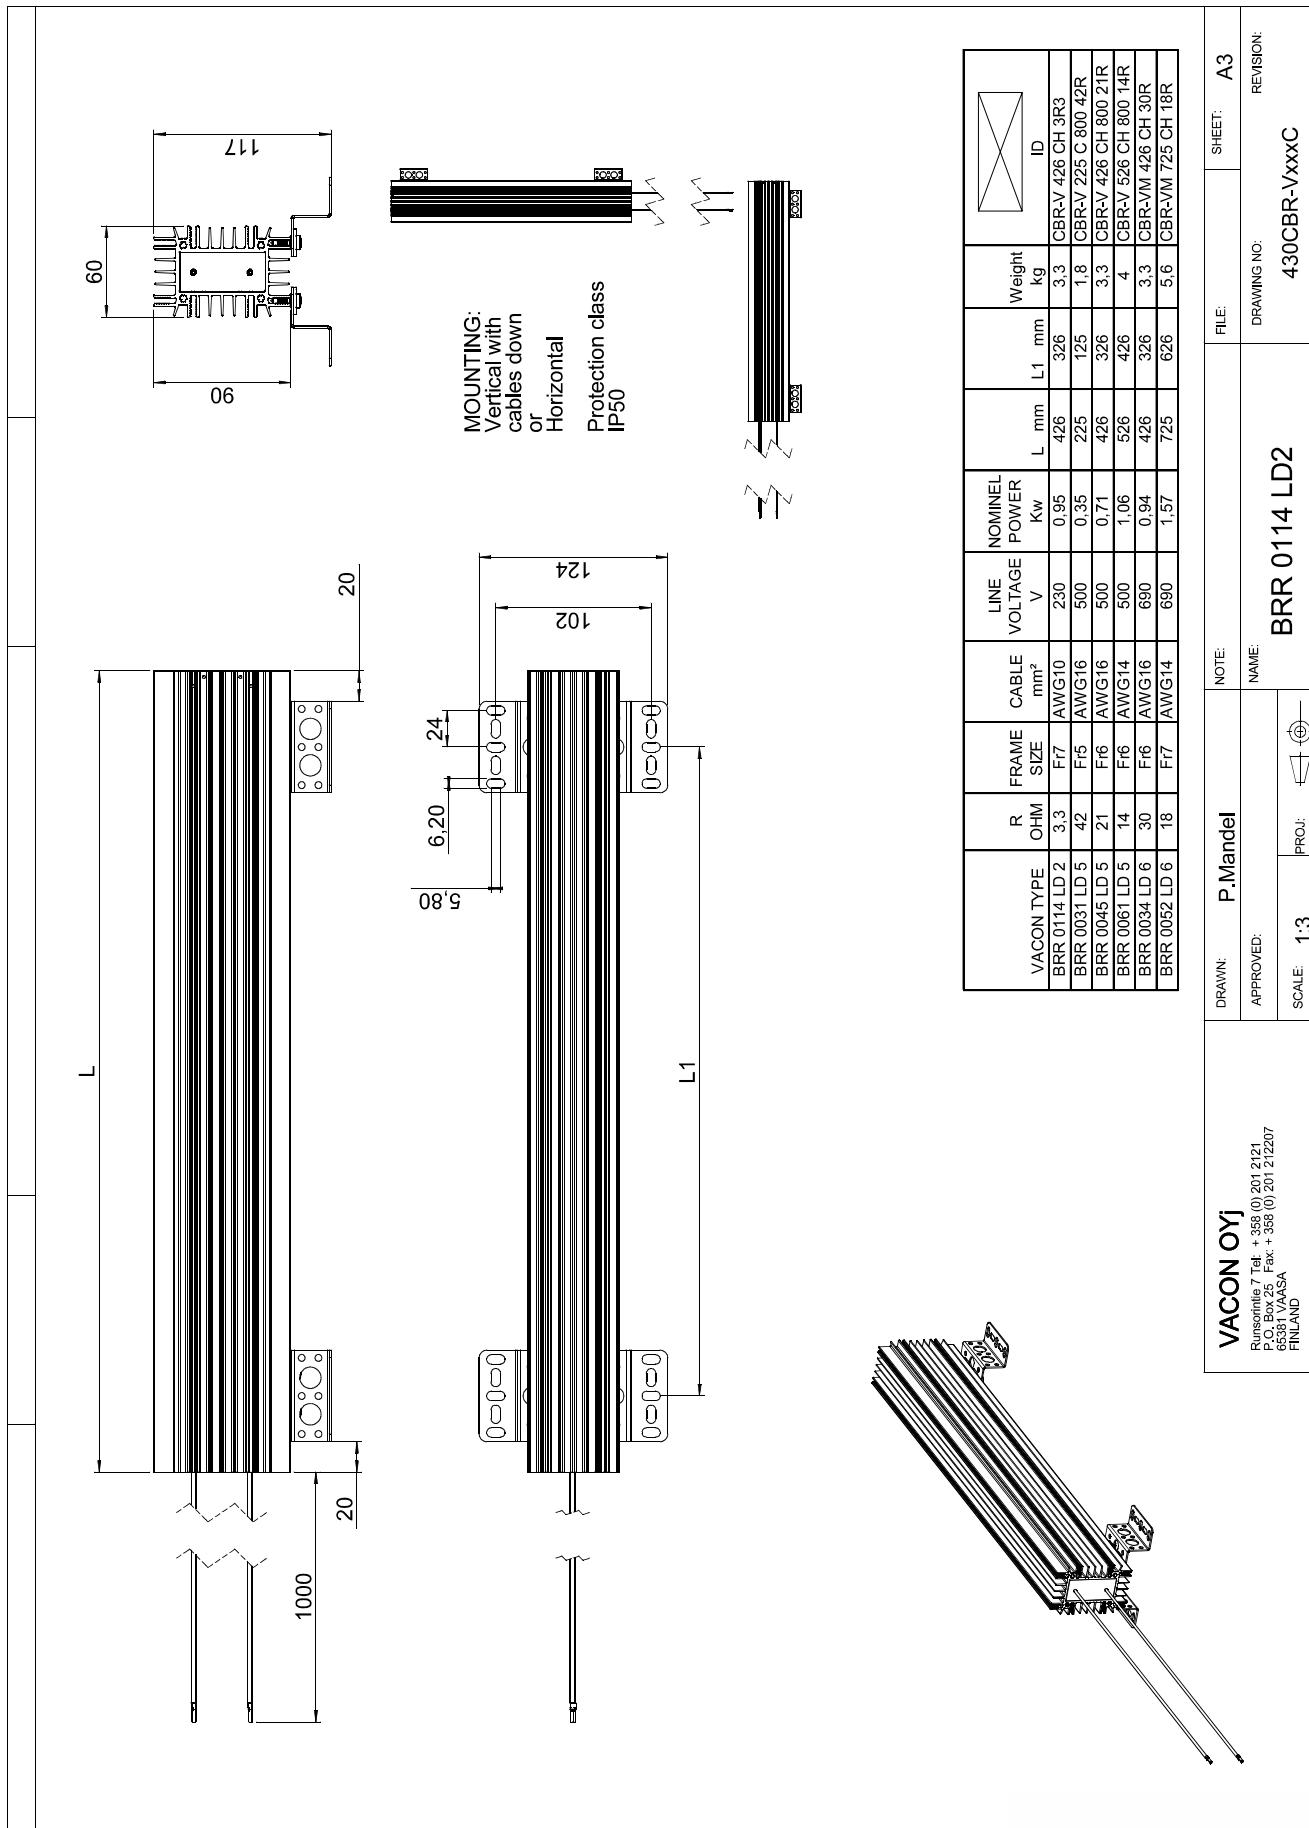

0	0,5
2	0,8
4	1
6	2
8	3
10	5
12	8
14	13
16	19
18	32
20	52

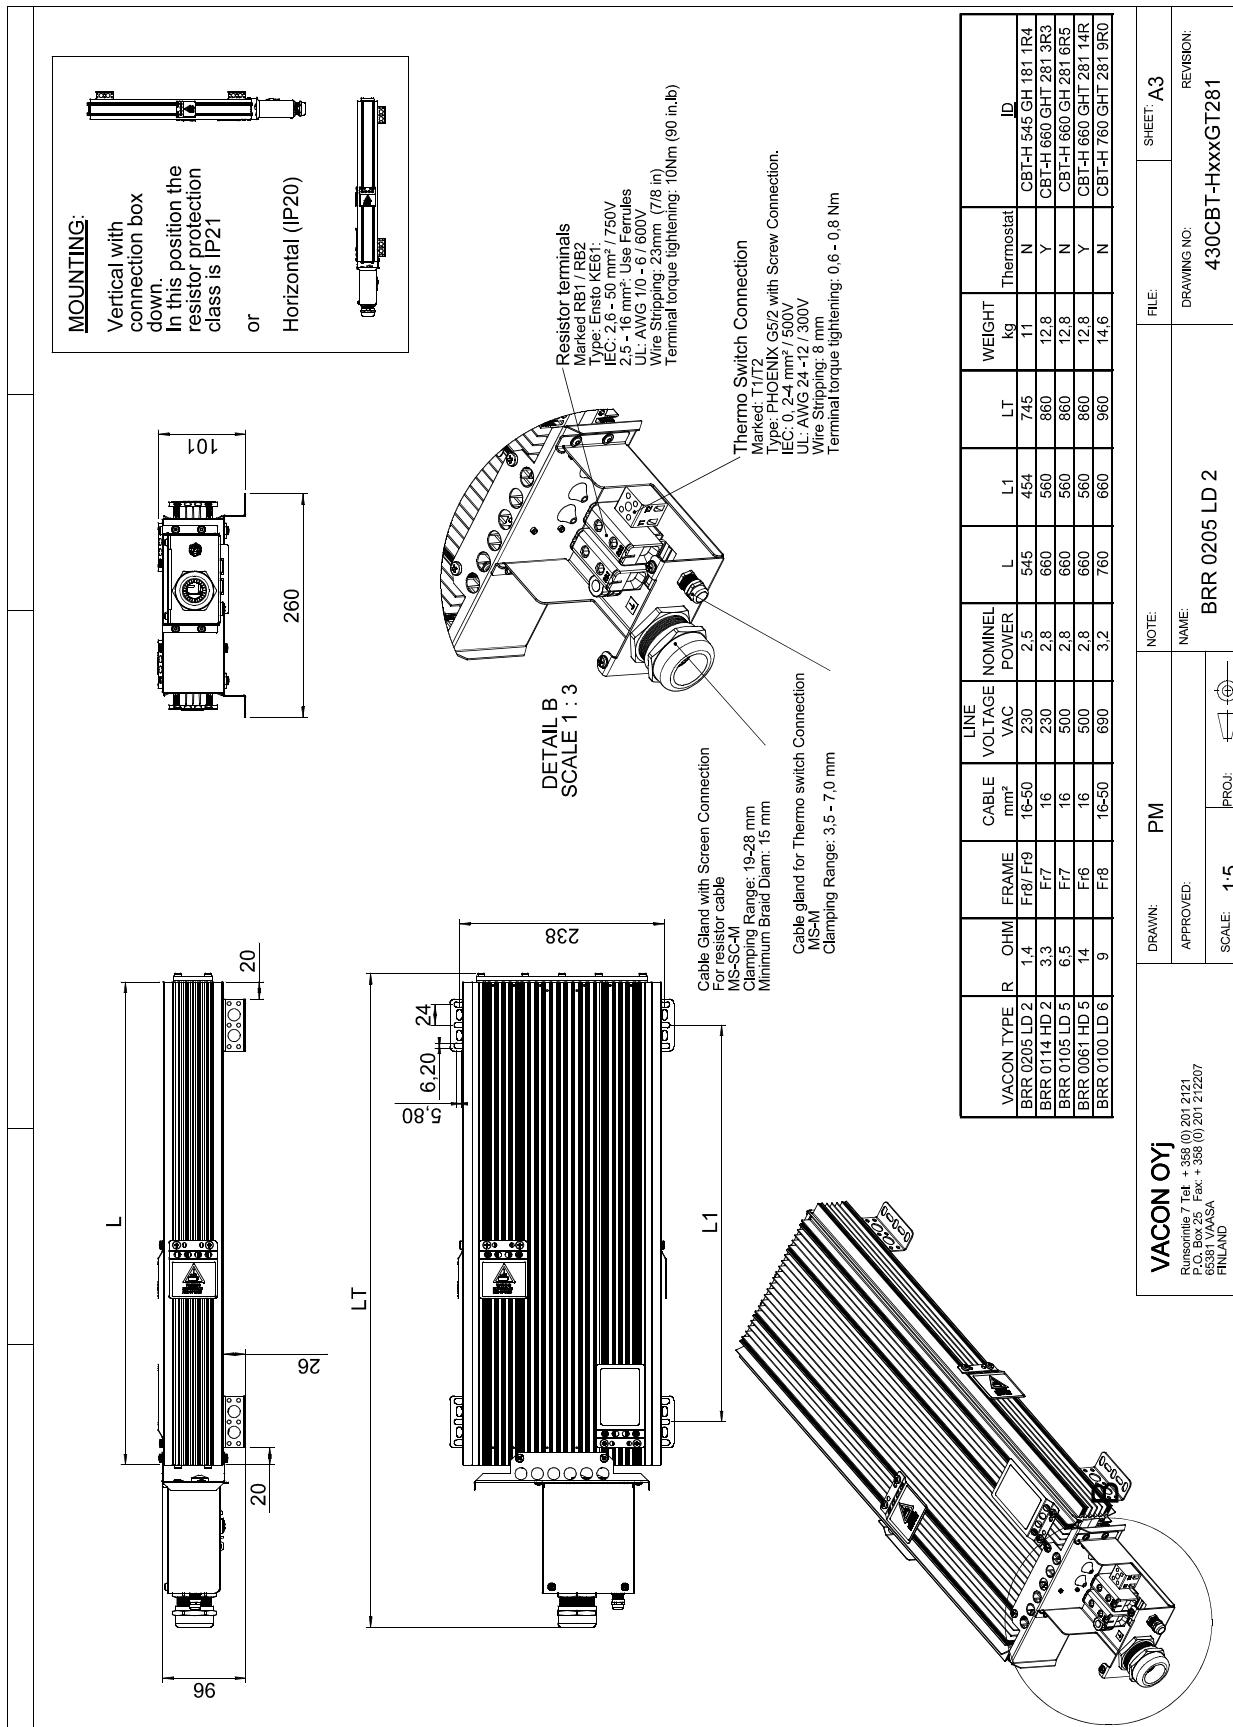

Thermal protection:

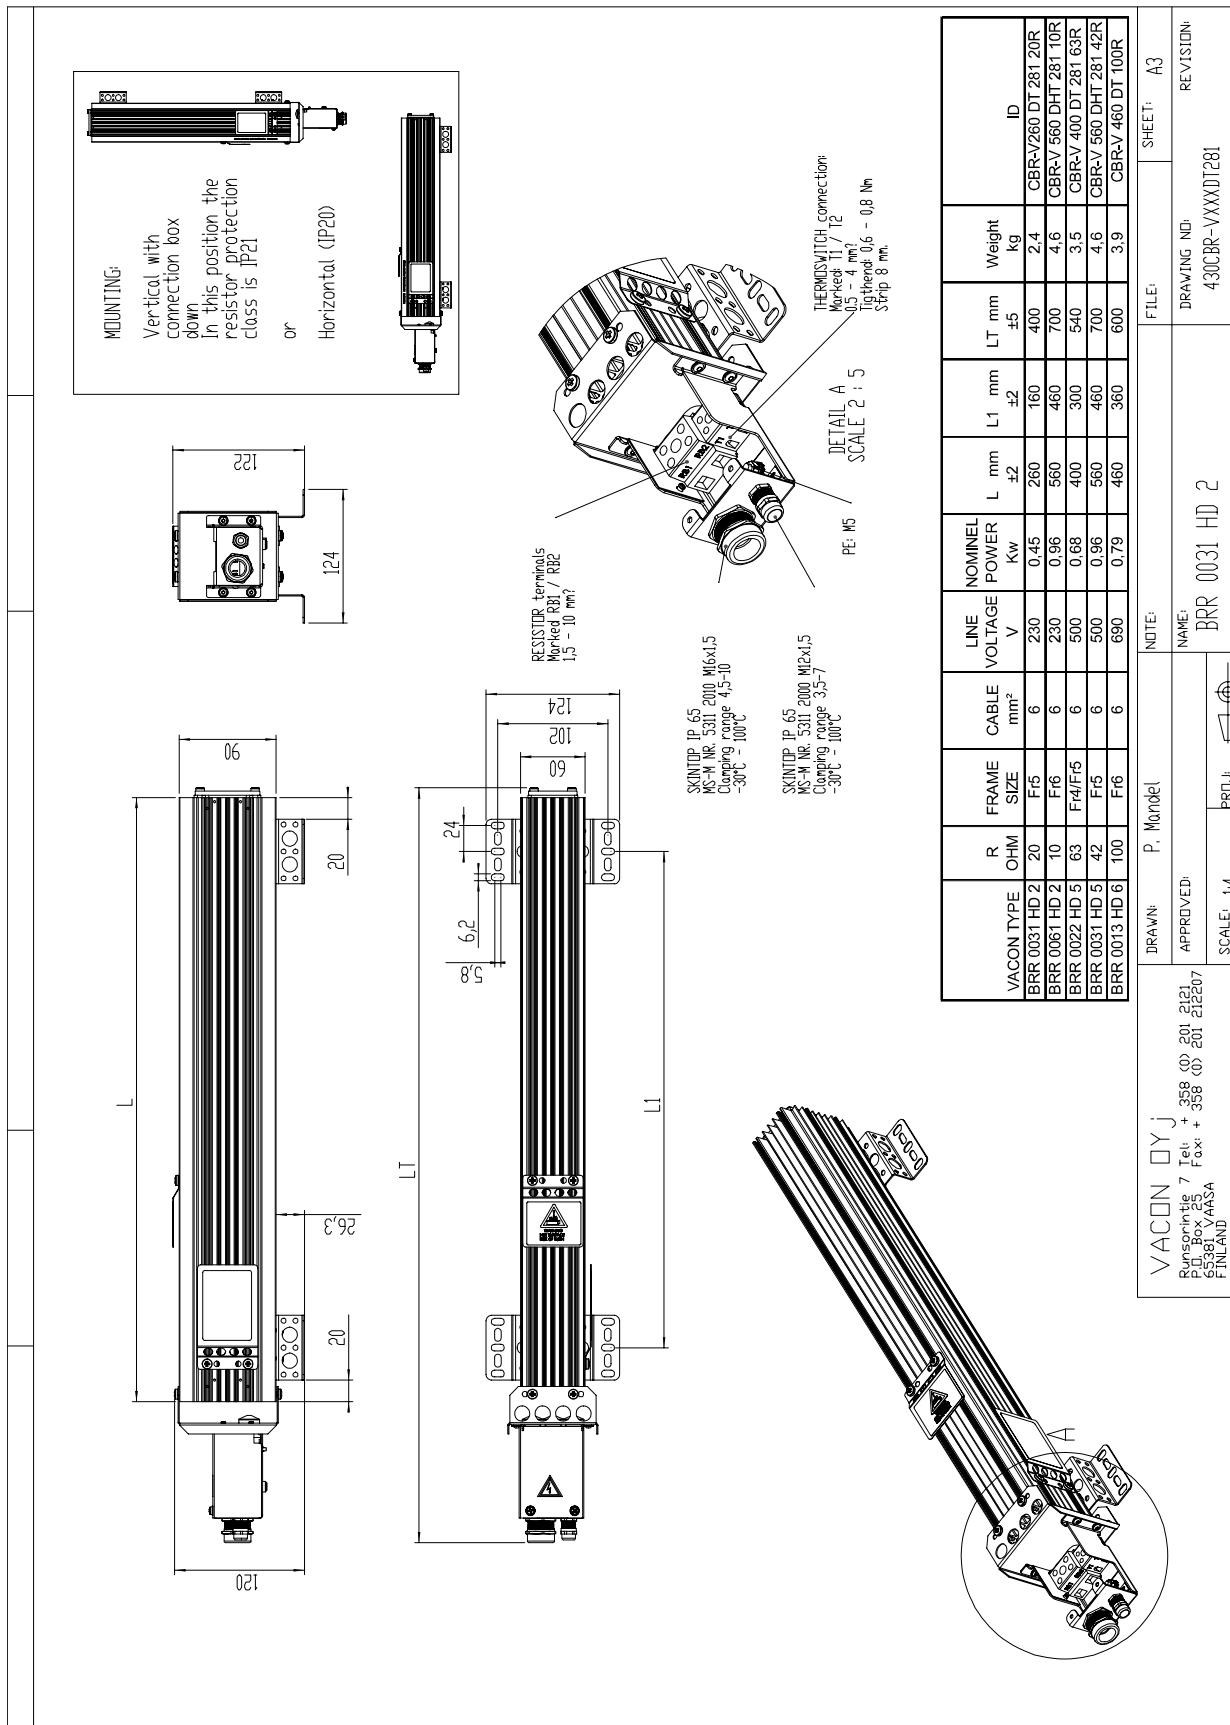

The thermal protection in the resistors should be connected to the external Fault input on the drive.

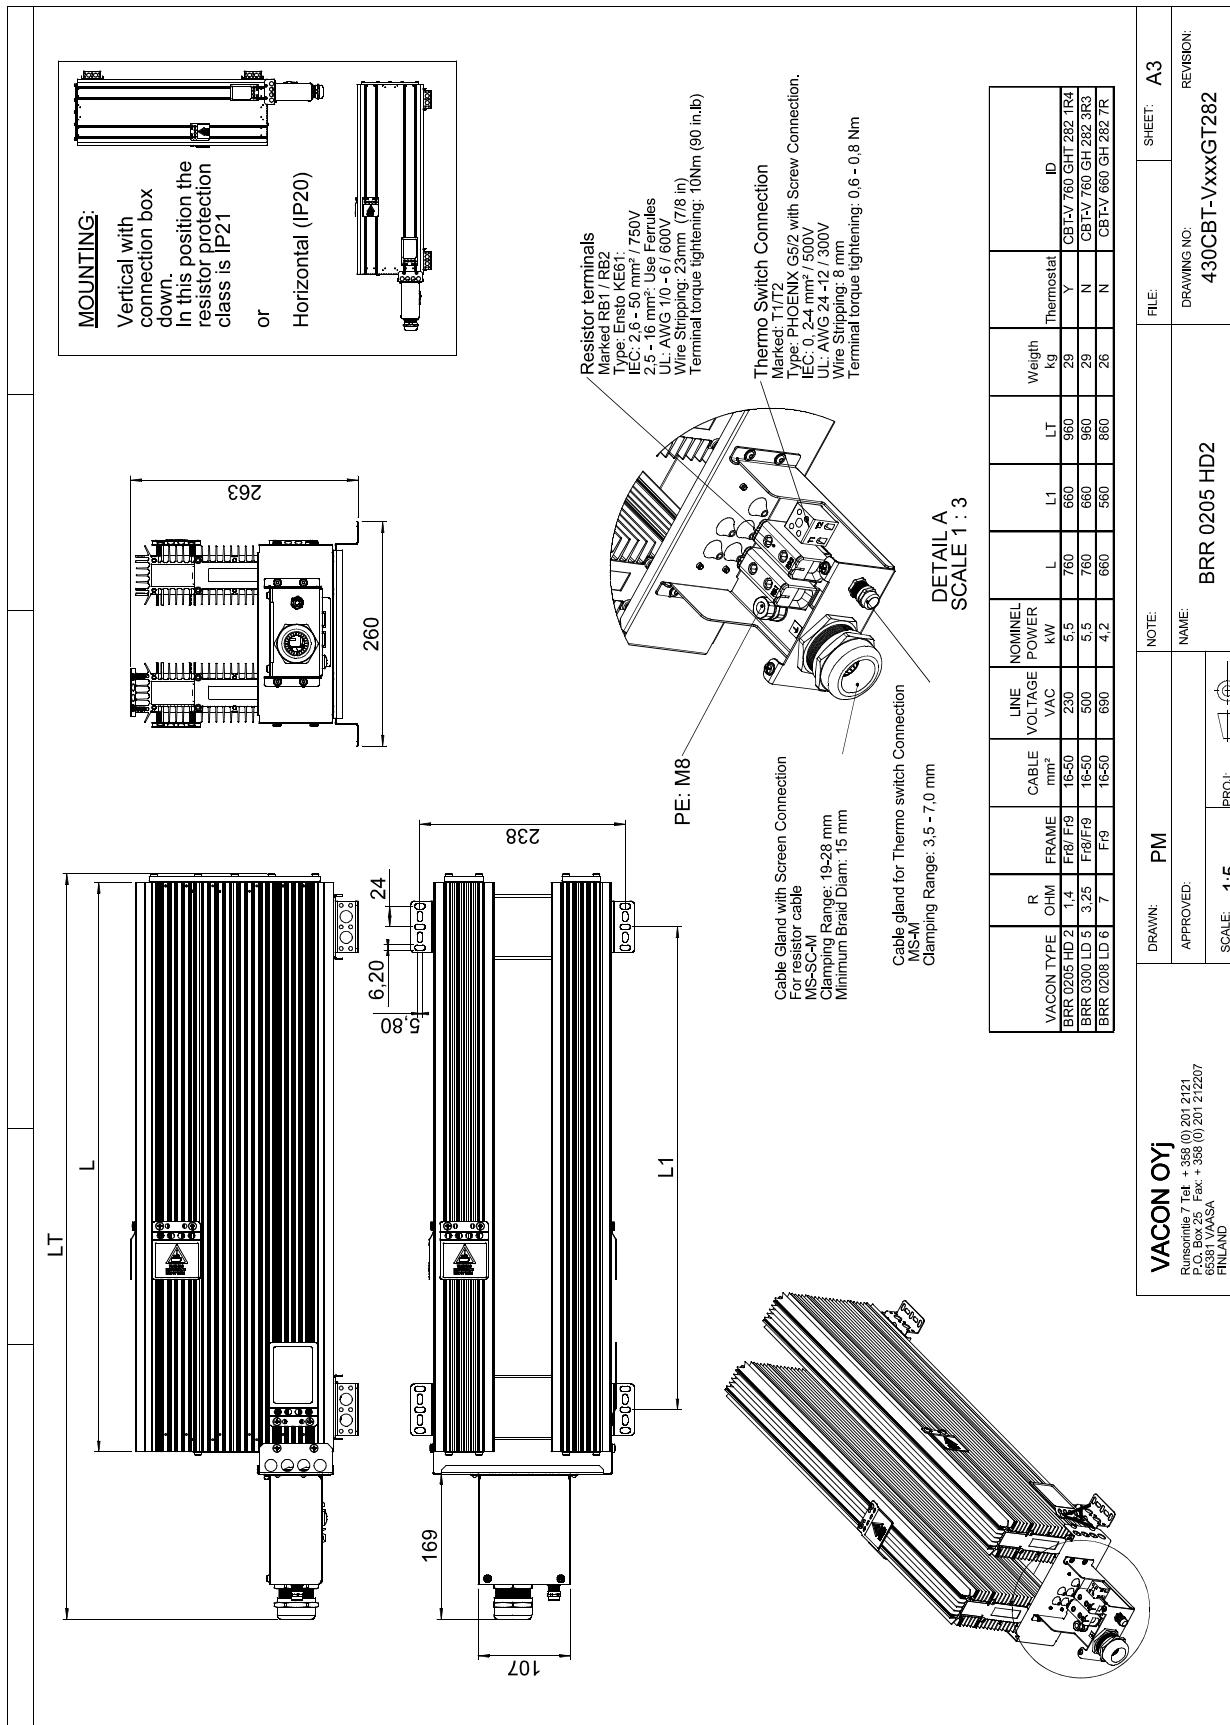

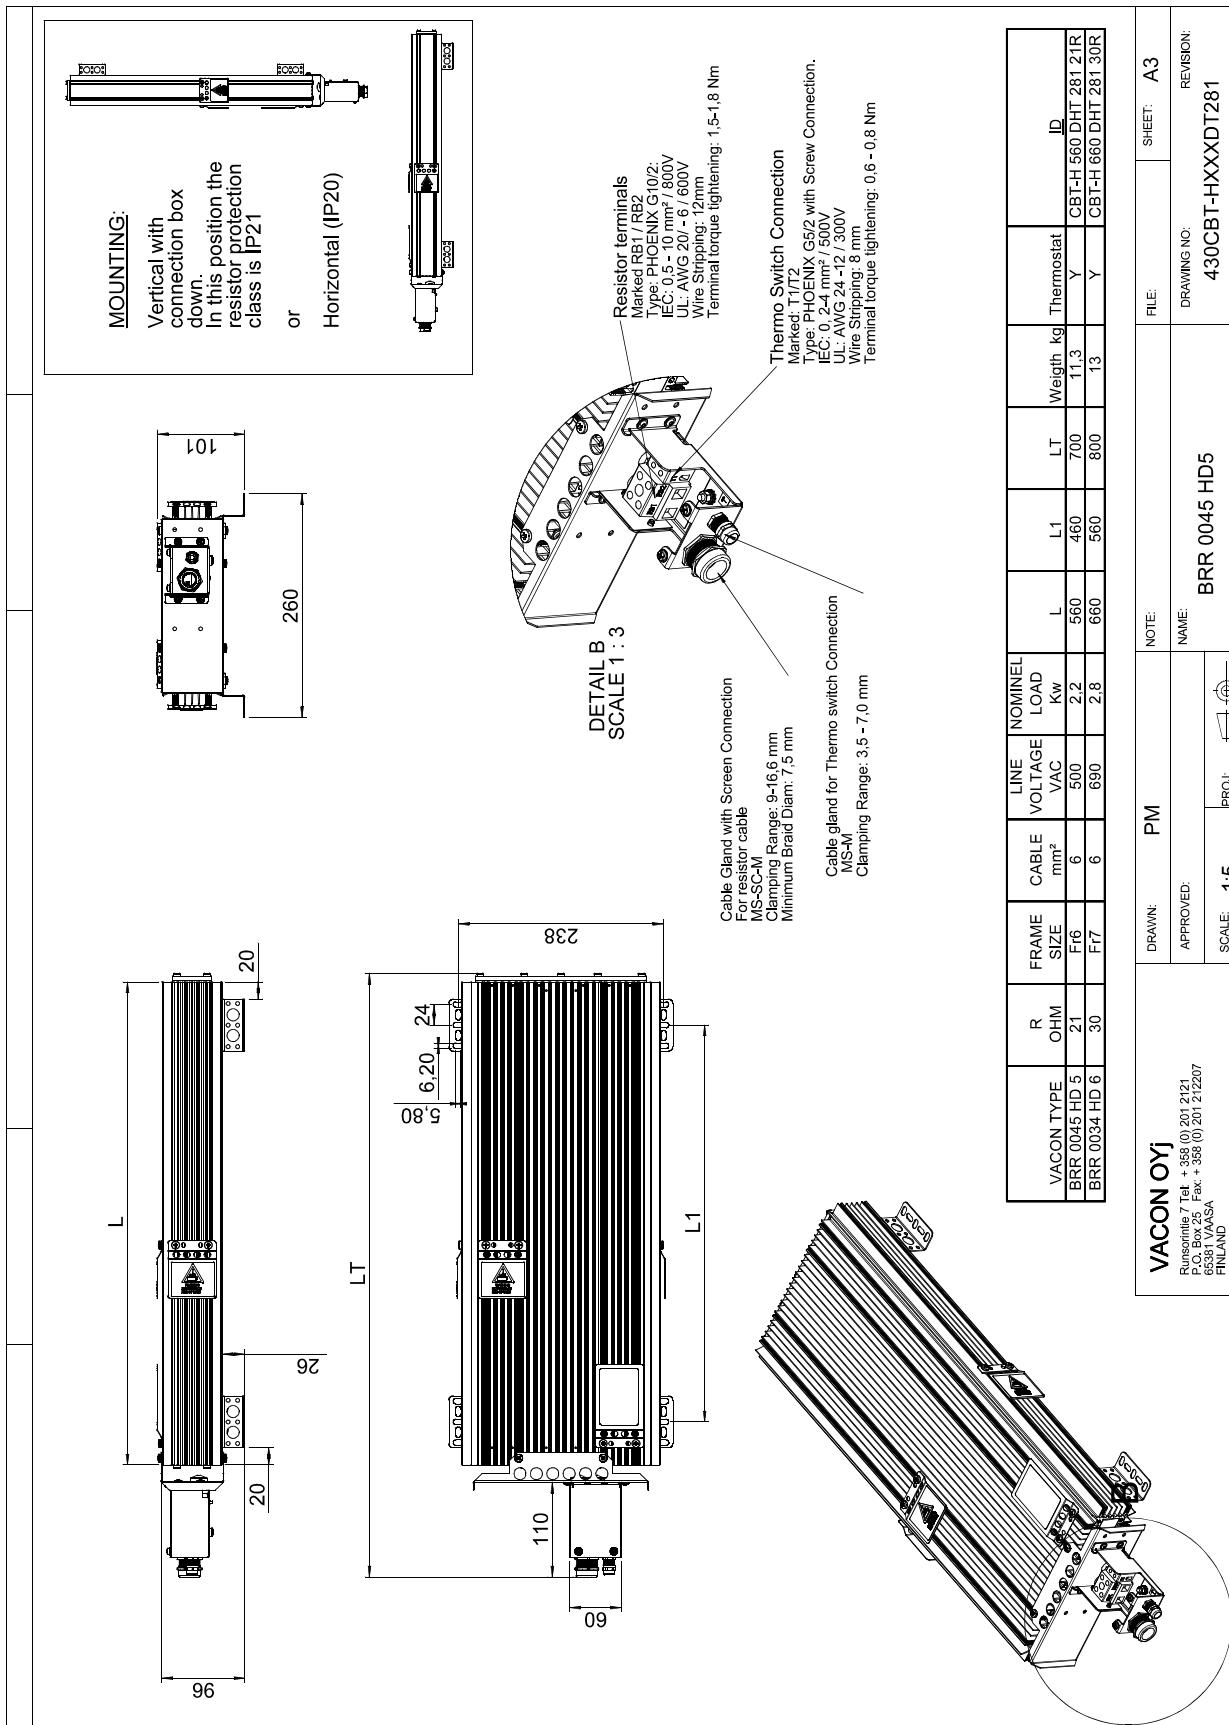

Vacon code	Ohm	FRAME	Connection	Cable mm	Vac	Pn kW	Weight Kg
